1 Motivation

The present abstract reports on the state-of-the-art of the logic for contracts $\mathcal{CL}$, which we have been developing over the last few years. These research efforts have spread over several papers [7, 6, 3, 5], which we summarize here. We present also some current work. The main motivation for our work is to have a logic which expresses, at an abstract level, complex behavior (of concurrent programs, of communicating intelligent agents, of web services, or of legal contracts; just to name a few possible concretizations of the behaviors we think of). The purpose of this logic is, not only, to formalize such behaviors, but mainly to reason about their formalizations. Therefore we seek a decidable logic, so to have hopes for automation; i.e., to do automated model checking and run-time monitoring.

Legal contracts talk about behavior which encompasses all the other behaviors that we mentioned before. Therefore, a formalism for reasoning about legal contracts offers the opportunity to reason about the other behaviors too, by instantiation (and possibly small changes). We have developed a logic (which we call $\mathcal{CL}$) designed to represent and reason about contracts (being that software contracts, web services, interfaces, or communication protocols). $\mathcal{CL}$ combines deontic logic (i.e., the logic of legal contracts) [8] with propositional dynamic logic (PDL, the logic of actions) [2]. $\mathcal{CL}$ applies the deontic and dynamic modalities exclusively over actions.

Moreover, $\mathcal{CL}$ extends the (regular) actions that PDL talks about, with a concurrency operator to model the notion of actions “done at the same time”. We adopt the synchrony model of concurrency of Milner’s SCCS calculus [4]. Synchrony is easy to integrate with the regular operations on actions: choice, sequence, and repetition. To be more precise, the synchrony model takes the assumption that time is discrete and that basic actions are instantaneous. Moreover, at each time step each and all the concurrent components perform instantaneously a single action (no idling being permitted unless explicitly stated); i.e. the system is considered eager and active. This is opposed to the standard asynchrony where two concurrent systems proceed at indeterminate relative speeds (i.e. their actions may have different non-correlated durations).

$\mathcal{CL}$ combines the expressive power of PDL (which subsumes Hoare logic for talking about sequential programs) with a natural notion of concurrent actions. On top, $\mathcal{CL}$ incorporates the expressive deontic modalities obligation, permission, and prohibition applied over actions. The actions of $\mathcal{CL}$ are abstract entities which can be instantiated to, e.g., communication primitives, assignments, or tests.

⋆ Partially supported by the Nordunet3 project “COSoDIS – Contract-Oriented Software Development for Internet Services” (http://www.ifi.uio.no/cosodis/).
The syntax of $\mathcal{CL}$ is defined by the grammar in Table 1. We call a formula $C$ a contract clause (or plainly contract). A contract is built up from propositional constants $\phi$, obligations $O_{\mathcal{C}}(\alpha)$ of actions $\alpha$, permissions $P(\alpha)$, and prohibitions $F_{\mathcal{C}}(\alpha)$ (i.e., the deontic modalities applied over actions $\alpha$). $\mathcal{CL}$ includes directly in the definition of the obligation and prohibition the reparations $C$ in case of violations (i.e., whenever $\alpha$ is not performed, in the case of an obligation). Contracts are combined using the standard Boolean operators $\rightarrow$ and $\bot$ from the propositional constants $\phi$. Therefore, we do not have the full power of PDL but only that of poor tests PDL.

The formulas of the logic are given a model theoretic semantics in terms of (what we call) normative structures.

**Definition 1.** A normative structure $K^N = (W, \rho, \nu, \nu')$ is a deterministic Kripke structure with a marking function $\nu : W \rightarrow 2^P$ which marks each state with one or several markers from $\Psi = \{v_a, \bullet_a \mid a \in A_B\}$. The marking function and the markers are needed to identify obligatory (i.e. $\circ$) and prohibited (i.e. $\bullet$) actions. The labels of the normative structure are subsets of basic actions $A_B$. Therefore, we compare them using set inclusion (and call one label bigger than another).

We give below the definition of satisfaction of formula $C$ w.r.t. a pointed normative structure $K^N, i \models C$. The semantics for $O_{\mathcal{C}}$ has basically two parts. The first part (lines one to four) gives the interpretation of the obligation. Line one says, using the simulation relation $S_i$, how to walk on the normative structure depending on the tree interpretation $I(\alpha)$ of the action. The precise definitions of these concepts are out of the scope of this paper. Lines two and three say how the states must be marked with $\circ$. The second part of the semantics is the last line which handles our notion of reparation in case of violations of obligations. The negation of an action $\overline{\alpha}$ encodes all possible ways of violating $O(\alpha)$. Thus, at the end of each of these the reparation must be enforced.

1. $K^N, i \models O_{\mathcal{C}}(\alpha)$ iff $I(\alpha) S_i K^N$, and
2. $\forall t \stackrel{\gamma}{\rightarrow} t' \in I(\alpha), \forall s \stackrel{\gamma'}{\rightarrow} s' \in K^N$ s.t. $t S s \land \gamma \subseteq \gamma'$ then
3. $\forall a \in \gamma, v_a \in g(s')$, and
4. $\forall s' \in K^N, i \models C$ iff $\gamma' \in I(\alpha)$, $\forall a \in \gamma$ then $v_a \notin g(s')$, and
5. $K^N, s \models C \forall s \in N$ with $t S^s s \land t \in leaves(I(\overline{\alpha}))$.

The $\mathcal{CL}$ logic enjoys the properties given in Proposition 1 (which make the starting point for the axiomatization that we are currently working on) and avoids some common contradictions, where $\alpha \#_C \alpha'$ means that the two actions are conflicting.

Proposition 1 (validities). The following statements hold:

\[
\begin{align*}
\models \neg O_C(0) & \quad \models O_C(1) \quad \models O_C(\alpha) \land O_C(\alpha') \rightarrow O_C(\alpha \times \alpha') \\
\models P(\alpha) \rightarrow \neg F_C(\alpha) & \quad \models F_C(\alpha) \rightarrow F_C(\alpha \times \alpha') \\
\text{if } \alpha = \alpha' & \text{ then } \models O_C(\alpha) \leftrightarrow O_C(\alpha') \\
\models O_C(\alpha) \rightarrow \neg F_C(\alpha) & \quad \models P(\alpha) \land P(\alpha')
\end{align*}
\]

The following point out conflicts that are avoided in $CL$:

\[
\begin{align*}
\models \neg (O_C(\alpha) \land F_C(\alpha)) & \quad \models \neg (P(\alpha) \land F_C(\alpha)) \\
\text{if } \alpha \neq \alpha' & \text{ then } \models \neg (O_C(\alpha) \land O_C(\alpha'))
\end{align*}
\]

Theorem 1 (tree model property). Given a contract $C$ and a pointed normative structure $K^N, i$ then we can construct an associated tree structure $T K^N, i$ s.t.

\[
T K^N, i \models C \iff K^N, i \models C.
\]

We show that $CL$ is decidable by showing that it has the finite model property. Note first that it is rather hard to use the filtration technique in our case because we do not know what are subformulas of an obligation of a complex action like $O_C(\alpha - (b + c))$. We use the selection technique for proving the finite model property [1, sec.2.3].

Theorem 2 (finite model property). For a formula $C$ of depth $k$, if $T K^N, i \models C$ then $C$ holds in $T K^N, i$ restricted to paths of maximum depth $k$ (i.e. where all nodes of depth $> k$ are removed). Hence, if a formula has a model then it has a finite model.

The depth is calculated as $d(C) = \max(l(\alpha) \mid \forall \alpha \in C)$, which multiplies the nesting degree of a formula $d(C)$ (which counts the number of nesting of $O$ or $F$ inside the reparations; e.g. $d(O_F(\alpha)(\beta)) = 2$) with the maximal length of the actions that appear in the formula.

Current work. We are now working on a Hilbert-style axiomatization for $CL$. This opens the way for a proof system for $CL$ which would complement the model checking and the run-time monitoring that we have.
